# Problem Statement

## E-Commerce Business Intelligence & Customer Analytics Platform

Modern e-commerce companies generate massive amounts of data from customers, orders, payments, deliveries, sellers, and product reviews. However, this data is often spread across multiple tables, making it difficult to extract meaningful insights that support business decisions. Without proper analysis, companies struggle to identify revenue-driving products, understand customer purchasing behaviour, evaluate seller performance, improve delivery efficiency, and enhance customer satisfaction.

The objective of this project is to build a complete Business Intelligence and Analytics solution using a real-world e-commerce dataset. The project will involve cleaning and transforming raw data, performing feature engineering, integrating the data into a relational database, and conducting SQL-based business analysis. Interactive Power BI dashboards will be developed to visualize key performance indicators (KPIs), uncover trends, and provide actionable recommendations that help improve sales performance, operational efficiency, customer retention, and overall business growth.
